Two experiments were conducted to determine if including DDGS in the diet reduces the incidence and/or severity of infection in growing pigs after a *L. intracellularis* challenge. In Experiment 1, eighty 17-d old weaned pigs were blocked by sex and weight and randomly allotted to one of four treatment groups: negative control (NC) - unchallenged, corn-soy diet; positive control (PC) - challenged, corn-soy diet; 10% DDGS diet (10D) – challenged; and 20% DDGS diet (20D) - challenged. Challenged pigs were orally inoculated with $1.5 \times 10^9$ *L. intracellularis* after a 4-wk pre-challenge period. On d 21 post-challenge, pigs were euthanized, lesions of intestinal mucosa was evaluated, and ileal tissue samples were analyzed by immunohistochemistry to determine presence and proliferation of *L. intracellularis*. Feeding DDGS did not beneficially affect lesion length, prevalence, proliferation of *L. intracellularis*, or severity of lesions ($P > .10$). In Experiment 2, 100 pigs were managed similarly to pigs in Experiment 1, except that the dosage of *L. intracellularis* was reduced to $8.0 \times 10^8$. Treatments consisted of NC and 4 challenge groups: PC, 10D, PC + AR (antimicrobial regimen), and 10D + AR. For AR treatments, diets contained 30 g/ton BMD® continuously, with Aureomycin® pulsed at 500 g/ton from d 3 pre-challenge to d 11 post-challenge. Feeding DDGS reduced ileum and colon lesion length and prevalence ($P < .05$), and reduced severity of lesions in the ileum ($P < .05$) and colon ($P < .10$) compared to other challenged pigs. Pigs fed AR had a lower prevalence and severity of lesions in the jejunum ($P < .05$), and tended to have reduced total tract lesion length ($P = .11$). No differences in length, severity, or prevalence of lesions were observed in 10D + AR pigs ($P > .15$), but fecal shedding of *L. intracellularis* was reduced on d 14 post-challenge ($P < .05$). No dietary effects on fecal shedding were observed by d 20 post-challenge ($P < .10$). Proportion of cells infected with *L. intracellularis* was reduced when DDGS ($P = .05$) or antimicrobials ($P = .10$) were fed. Dietary inclusion of DDGS may provide some benefit to growing pigs subjected to a moderate ileitis challenge, similar to a currently approved antimicrobial regimen, but not under conditions of a severe *L. intracellularis* challenge.
